

LinkedIn Content & Engagement Automation

n8n + LinkedIn API + AI

A centralized workflow that turns a content idea into an approved, scheduled and API-driven LinkedIn action — while supporting both the Founder Profile and Company Page.

LinkedIn operations are manual, repetitive and fragmented

The burden is not one difficult task — it is coordinating the same sequence again for every piece of content.

One workflow, two destinations, one control layer

The architecture keeps account routing, content routing and execution inside the same reusable automation system.

Design principle: AI prepares the communication, n8n controls the process, the LinkedIn API performs the action, and human approval remains at the decision points.

LinkedIn authorization enables permitted API actions

The developer application establishes the integration context; OAuth provides the authorized access used by the workflow.

From a content request to an approved publishing action

The workflow is intentionally sequential: context first, generation and checks next, execution last.

Implementation: the actual n8n workflow

The canvas shows the architecture becoming executable: the request enters once, is normalized, routed, then mapped to specific API sequences.

Actual n8n workflow canvas (implementation reference)

- 1 TRIGGER**
Receives the workflow request and starts the automation.
- 2 EDIT FIELDS**
Creates a consistent request object: accountType, postType, topic, tone, publishAt and media.
- 3 SWITCH NODE**
Applies the decision logic and sends the request into the correct publishing branch.
- 4 HTTP REQUEST NODES**
Performs direct API operations for identity retrieval, media handling and publishing.
- 5 MEDIA PATHS**
Separates Text, Image, Video and Article flows so each publishing sequence stays modular.

Decision logic ≠ API execution

The content format determines the API sequence

The account-routing architecture stays constant; the downstream media steps change according to postType.

AI converts business context into drafts; n8n turns approval into execution

The intelligence and orchestration layers remain separate so the content process is explainable and controllable.

Engagement continues after publishing — human judgment stays at key points

The system can classify and draft routine responses, while sensitive or high-value interactions move to human review.

The automation removes repetitive engagement work without removing accountability for public communication.

From fragmented execution to a controlled LinkedIn system

The result is a reusable process around content, accounts, API execution, scheduling, engagement and approval.

EXPECTED OUTCOME

- 

Operational efficiency Less repeated coordination around each post
- 

Consistency A repeatable process for founder and company communication
- 

Control Approval remains visible at the important decision points
- 

Extensibility New formats, account branches or analytics can be added modularly

AI prepares · n8n orchestrates · LinkedIn API executes · Humans decide
